Applicant argues a single issue with respect to the current rejection. In particular applicant appears to argue the limitation "wherein the buffer includes a differential amplifier that generates an output logic signal from a differential signal and filters out input noise by introducing asymmetry into the transfer characteristic" or equivalent, see e.g., second full paragraph of applicant's arguments on page 12. As pointed out by applicant, the actual claim limitation is not the above issue but instead, "suppressing effects of input noise on the output logic signals by skewing an output amplifier transfer characteristic". The above limitation is met since the output of the differential amplifier as taught by Jeong is naturally skewed based on the first and second amplification processes. In particular, Jeong teaches that "the parallel combination of first amplification stage 100 and second amplification stage 200 compensates for any asymmetries inherent in the amplification stage, see e.g., column 7, lines 5-52 (i.e., each amplification stage has a transfer characteristic). Thus since asymmetries are compensated for, the effects of input noise, is suppressed. Hence Jeong teaches the above limitation since noise is suppressed based on the first and second amplification stages. The examiner further agrees that how an output is skewed with respect to introducing asymmetries (in view of e.g. applicant's figure 6 and applicant's arguments on page 12, second paragraph) is not further taught by Jeong. However, the examiner also notes that how an output is skewed is also not further recited in the claims at issue above.
